
FINAL REPORT

The monthly workforce cost trend shows significant year-end spikes in both 2023 and 2024, particularly during November and December. Based on the cost breakdown, these increases were mainly driven by annual bonus payments.

The actual monthly workforce cost increased sharply during these periods, while most regular months remained relatively stable around the normal operating cost range. The 3-month moving average also increased during the year-end periods, reflecting the impact of the high-cost months on the short-term cost trend.

However, the exponential smoothing trend did not increase as sharply as the actual cost. This indicates that the year-end spikes are likely temporary or seasonal, rather than a permanent increase in the monthly workforce cost baseline.

From a decision-making perspective, the actual cost should be used for cash flow planning and variance investigation, while the exponential smoothing trend can be used as a normalized baseline for future cost planning. The gap between actual cost and the smoothed trend should be reviewed to understand the impact of bonus payments and other exceptional cost drivers.
